Common Types of Electromagnetic Solved Problems

This section explores typical problems encountered in electromagnetism, along with their step-by-step solutions.

1. Electric Field due to a Point Charge

Problem statement:

Calculate the electric field at a point P located 5 meters from a point charge of $2 \times 10^{-6} \text{ C}$.

Solution:

- Given data:
- Charge, $(q = 2 \times 10^{-6} \text{ C})$
- Distance, $(r = 5 \text{ m})$

- Relevant formula:

$E = \frac{k|q|}{r^2}$

$$E = \frac{k|q|}{r^2}$$

where $(k = 9 \times 10^9 \text{ Nm}^2/\text{C}^2)$

where $(k = 9 \times 10^9 \text{ Nm}^2/\text{C}^2)$

- Calculation:

$E = \frac{9 \times 10^9 \times 2 \times 10^{-6}}{(5)^2} = \frac{18 \times 10^3}{25} = 720 \text{ N/C}$

$$E = \frac{9 \times 10^9 \times 2 \times 10^{-6}}{(5)^2} = \frac{18 \times 10^3}{25} = 720 \text{ N/C}$$

- Direction:

Radially outward from the charge if the charge is positive.

Key takeaway:

This problem illustrates Coulomb's law and the inverse-square nature of electric fields.

2. Magnetic Field due to a Long Straight Current-Carrying Wire

Problem statement:

Determine the magnetic field at a point 10 cm from a long straight wire carrying a current of 5 A.

Solution:

- Given data:

- Distance from wire, $(r = 0.1 \text{ m})$

- Relevant formula:

$\{$

$$B = \frac{\mu_0 I}{2 \pi r}$$

$\}$

where $(\mu_0 = 4\pi \times 10^{-7} \text{ T} \cdot \text{m/A})$

- Calculation:

$\{$

$$B = \frac{4\pi \times 10^{-7} \times 5}{2 \pi \times 0.1} = \frac{2 \times 10^{-6} \times 5}{0.2} = \frac{10 \times 10^{-6}}{0.2} = 50 \times 10^{-6} \text{ T} = 50 \mu\text{T}$$

$\}$

- Direction:

Use the right-hand rule to determine the magnetic field direction around the wire.

Key takeaway:

This problem exemplifies the application of Ampère's law in calculating magnetic fields.

3. Induced emf using Faraday's Law

Problem statement:

A coil with 100 turns experiences a change in magnetic flux from 0.5 Wb to 0 Wb in 0.2 seconds. Find the induced emf in the coil.

- Change in flux, $(\Delta \Phi = 0.5 - 0 = 0.5, \text{ Wb})$
- Time interval, $(\Delta t = 0.2, \text{ s})$

- Relevant formula:

[

$$\text{emf} = -N \frac{\Delta \Phi}{\Delta t}$$

]

- Calculation:

[

$$\text{emf} = -100 \times \frac{0.5}{0.2} = -100 \times 2.5 = -250, \text{ V}$$

]

- Interpretation:

The negative sign indicates the direction of induced emf as per Lenz's law.

Key takeaway:

This problem reinforces Faraday's law of electromagnetic induction.

Advanced Electromagnetic Problems and Their Solutions

While the above examples cover foundational problems, more complex scenarios involve multiple fields, boundary conditions, and wave propagation.

4. Determining Reflection and Transmission Coefficients at an Interface

Problem statement:

An electromagnetic wave traveling in air (permittivity ϵ_0) strikes a dielectric medium with permittivity ϵ_r . Calculate the reflection coefficient for normal incidence.

Solution:

- Given data:
- Incident medium: air, $\epsilon_1 = \epsilon_0$
- Transmission medium: dielectric, $\epsilon_2 = \epsilon_r \epsilon_0$

- Relevant formula:

[

$$R = \frac{E_{\text{reflected}}}{E_{\text{incident}}} = \frac{\eta_2 - \eta_1}{\eta_2 + \eta_1}$$

]

where $\eta = \sqrt{\frac{\mu}{\epsilon}}$

- Since magnetic permeability μ is approximately equal in both media:

[

$$R = \frac{\sqrt{\epsilon_1} - \sqrt{\epsilon_2}}{\sqrt{\epsilon_1} + \sqrt{\epsilon_2}}$$

]

- Calculation:

$$\Gamma$$

$$R = \frac{1 - \sqrt{\epsilon_r}}{1 + \sqrt{\epsilon_r}}$$

$$\Gamma$$

- Example:

If $(\epsilon_r = 4)$,

$$\Gamma$$

$$R = \frac{1 - 2}{1 + 2} = \frac{-1}{3} \approx -0.333$$

$$\Gamma$$

Key takeaway:

This problem illustrates wave reflection at dielectric boundaries, important in antenna design and optical fibers.

5. Calculation of Electromagnetic Wave Propagation in a Medium

Problem statement:

Determine the wavelength of a 10 MHz electromagnetic wave propagating in a medium with relative permittivity $(\epsilon_r = 4)$.

Solution:

- Given data:
- Frequency, $(f = 10 \times 10^6 \text{ Hz})$
- Speed of light in vacuum, $(c = 3 \times 10^8 \text{ m/s})$
- Relative permittivity, $(\epsilon_r = 4)$

- Speed of wave in medium:

$$\Gamma$$

$$v = \frac{c}{\sqrt{\epsilon_r}} = \frac{3 \times 10^8}{\sqrt{2}} = 1.5 \times 10^8 \text{ m/s}$$

\\

- Wavelength:

\\

$$\lambda = \frac{v}{f} = \frac{1.5 \times 10^8}{10 \times 10^6} = 15 \text{ m}$$

\\

Key takeaway:

Wave propagation characteristics depend heavily on medium properties, affecting antenna and transmission line design.

To illustrate the learning process, this section covers detailed solutions to representative problems from each category. Each example emphasizes critical thinking, step-by-step calculation, and the conceptual understanding necessary to master similar questions.

Electrostatics Problem: Electric Field due to a Continuous Charge Distribution

Problem Statement:

Calculate the electric field at a point (P) located 5 meters from a uniformly charged rod of length 10 meters, which carries a total charge of $20 \text{ } \mu\text{C}$. The rod lies along the x-axis from $(x = 0)$ to $(x = 10)$ meters. Assume the point (P) is located at $(0, 5)$ meters.

Solution Approach:

- Identify the charge distribution:

Since the charge is uniformly distributed, the linear charge density (λ) is:

[

$$\lambda = \frac{Q}{L} = \frac{20 \times 10^{-6} \text{ C}}{10 \text{ m}} = 2 \times 10^{-6} \text{ C/m}$$

]

- Set up the coordinate system:

Let the rod extend from $(x' = 0)$ to $(x' = 10 \text{ m})$.

Point (P) is at $(0, 5 \text{ m})$.

- Express the differential charge element:

A small element (dx') at position (x') has charge:

[

$$dq = \lambda dx'$$

]

- Calculate the differential electric field $(d\vec{E})$:

The electric field contribution at (P) due to (dq) is:

[

$$d\vec{E} = \frac{1}{4\pi\epsilon_0} \frac{dq}{r^2} \hat{r}$$

]

where (r) is the distance from (dq) to (P) , and $(\hat{r})$ is the unit vector pointing from (dq) to (P) .

The position of (dq) is $(x', 0)$, and (P) is at $(0, 5)$, so:

[

$$r = \sqrt{(x' - 0)^2 + (0 - 5)^2} = \sqrt{x'^2 + 25}$$

]

The vector from (dq) to (P) :

[

$$\vec{r} = (0 - x', 5 - 0) = (-x', 5)$$

]

The magnitude:

[

$$r = \sqrt{x'^2 + 25}$$

]

The unit vector $(\hat{r})$:

[

$$\hat{r} = \frac{\vec{r}}{r} = \left(\frac{-x'}{r}, \frac{5}{r} \right)$$

]

- Express the differential field components:

[

$$dE_x = \frac{1}{4\pi\epsilon_0} \frac{dq}{r^2} \times \frac{-x'}{r} = \frac{1}{4\pi\epsilon_0} \frac{dq}{r^3} (-x')$$

]

\[

$$dE_y = \frac{1}{4\pi\epsilon_0} \frac{dq}{r^2} \times \frac{5}{r} = \frac{1}{4\pi\epsilon_0} \frac{dq}{r^3} \quad (5)$$

\]

- Integrate over the length of the rod:

\[

$$E_x = \int_0^{10} dE_x = -\frac{\lambda}{4\pi\epsilon_0} \int_0^{10} \frac{x'}{(x'^2 + 25)^{3/2}} dx'$$

\]

\[

$$E_y = \frac{\lambda}{4\pi\epsilon_0} \int_0^{10} \frac{5}{(x'^2 + 25)^{3/2}} dx'$$

\]

- Perform the integrations:

Standard integrals yield:

- For (E_x) :

\[

$$\int \frac{x'}{(x'^2 + a^2)^{3/2}} dx' = -\frac{1}{\sqrt{x'^2 + a^2}}$$

\]

- For (E_y) :

\[

$$\int \frac{dx'}{(x'^2 + a^2)^{3/2}} = \frac{x'}{a^2 \sqrt{x'^2 + a^2}}$$

]

with $(a = 5 \text{ m})$.

Calculating:

[

$$E_x = -\frac{\lambda}{4\pi\epsilon_0} \left[-\frac{1}{\sqrt{x'^2 + 25}} \right]_0^{10} = \frac{\lambda}{4\pi\epsilon_0} \left(\frac{1}{\sqrt{10^2 + 25}} - \frac{1}{\sqrt{0 + 25}} \right)$$

]

[

$$E_x = \frac{2 \times 10^{-6}}{4\pi \times 8.854 \times 10^{-12}} \left(\frac{1}{\sqrt{125}} - \frac{1}{5} \right)$$

]

Similarly,

[

$$E_y = \frac{\lambda}{4\pi\epsilon_0} \times 5 \times \left[\frac{x'}{25 \sqrt{x'^2 + 25}} \right]_0^{10}$$

]

Calculate the bounds:

[

$$\frac{10}{25 \sqrt{125}} = \frac{10}{25 \times 11.1803} \approx \frac{10}{279.507} \approx 0.0358$$

]

At 0:

$$\frac{0}{25 \times 5} = 0$$

$$\frac{2 \times 10^{-6}}{4\pi \times 8.854 \times 10^{-12}} \times 5 \times 0.0358$$

Thus:

$$E_y = \frac{2 \times 10^{-6}}{4\pi \times 8.854 \times 10^{-12}} \times 5 \times 0.0358$$

$$\frac{2 \times 10^{-6}}{4\pi \times 8.854 \times 10^{-12}} \times 5 \times 0.0358$$

Final numerical evaluation yields the magnitude and direction of the electric field at (P) .

Using Faraday's law, the induced emf is $\mathcal{E} = -d\Phi/dt$, where Φ is the magnetic flux through the loop. The negative sign indicates Lenz's law, opposing the change in flux. What is the purpose of solving boundary value problems in electromagnetic theory? Solving boundary value problems helps determine electric and magnetic fields in complex geometries by applying boundary conditions, ensuring accurate solutions in practical applications like antenna design and circuit analysis. How can one calculate the energy stored in an inductor in an electromagnetic circuit? The energy stored in an inductor is given by $U = (1/2) L I^2$, where L is the inductance and I is the current flowing through it.
