physical science 11 motion wordwise answers are essential for students aiming to master the fundamental concepts of motion in physics. Motion is a core topic in physical science, especially at the 11th-grade level, where students explore how objects move, the forces involved, and the mathematical descriptions of motion. Understanding motion not only helps students excel in exams but also builds a solid foundation for advanced scientific studies. This article provides comprehensive insights into physical science 11 motion wordwise answers, covering key concepts, definitions, and explanations to enhance your learning and prepare you for assessments.

Understanding Motion in Physical Science 11

Motion is the change in position of an object over time relative to a reference point. In physical science 11, the study of motion involves analyzing how objects move, the types of motion, and the factors affecting movement. Wordwise answers help clarify these concepts in simple language, making complex ideas more accessible.

Key Concepts of Motion

To grasp motion thoroughly, students need to understand several fundamental concepts:

- **Displacement:** The shortest distance from the initial to the final position of an object, measured in a straight line.
- **Distance:** The total length of the path traveled by an object, regardless of direction.
- **Speed:** The rate at which an object covers distance, calculated as distance divided by time.
- **Velocity:** Speed with a direction; it indicates how fast and in which direction an object moves.
- **Acceleration:** The rate at which an object's velocity changes over time, either increasing or decreasing.

Types of Motion

Understanding different types of motion is crucial in physical science 11. These include:

- **Linear Motion:** Movement in a straight line. For example, a car moving on a straight highway.
- **Rotational Motion:** Movement around an axis, like a spinning top or the Earth rotating.

- **Oscillatory Motion:** Repetitive back-and-forth movement, such as a pendulum or a vibrating guitar string.

Wordwise Definitions and Explanations for Motion

In physical science 11, clear definitions help students understand and articulate concepts effectively. Here are some essential wordwise answers related to motion:

Displacement

Displacement is the shortest distance from the starting point to the ending point of an object's movement, considering the direction. Unlike distance, which is scalar, displacement is a vector quantity, meaning it has both magnitude and direction. For example, if you walk 3 meters east and then 4 meters north, your displacement is the straight-line distance from your starting point to your ending point, which can be calculated using Pythagoras' theorem.

Speed and Velocity

Speed measures how fast an object moves without considering direction. It is calculated as:

$$\text{Speed} = \text{Distance traveled} / \text{Time taken}$$

Velocity, on the other hand, includes the direction of motion. It is given by:

$$\text{Velocity} = \text{Displacement} / \text{Time taken}$$

For instance, if a car travels 100 km in 2 hours heading north, its average speed is 50 km/h, and its average velocity is 50 km/h north.

Acceleration

Acceleration refers to how quickly an object's velocity changes. It can result from an increase (positive acceleration) or decrease (negative acceleration or deceleration) in speed, or a change in direction. The formula for acceleration is:

$$\text{Acceleration} = \text{Change in velocity} / \text{Time taken}$$

If a vehicle increases its velocity from 0 to 60 km/h in 5 seconds, its acceleration is 12 km/h per

second.

Equations of Motion in Wordwise Answers

In physical science 11, the equations of motion describe the relationships between displacement, initial velocity, final velocity, acceleration, and time. These are vital for solving problems related to motion.

First Equation of Motion

This relates initial velocity, final velocity, acceleration, and time:

$$v = u + at$$

Where:

- v = final velocity
- u = initial velocity
- a = acceleration
- t = time

Wordwise Explanation:

The final velocity of an object is equal to its initial velocity plus the product of acceleration and time. If a car starts from rest ($u=0$) and accelerates at 2 m/s^2 for 5 seconds, its final velocity is 10 m/s .

Second Equation of Motion

This relates displacement, initial velocity, time, and acceleration:

$$s = ut + \frac{1}{2} at^2$$

Where:

- s = displacement
- u = initial velocity
- a = acceleration
- t = time

Wordwise Explanation:

Displacement can be calculated by adding the initial velocity multiplied by time to half the product of acceleration and the square of time. For example, if a vehicle accelerates from rest at 2 m/s^2 over 4 seconds, the displacement is 16 meters.

Third Equation of Motion

This relates final velocity, initial velocity, acceleration, and displacement:

$$v^2 = u^2 + 2as$$

Where:

- v = final velocity
- u = initial velocity
- a = acceleration
- s = displacement

Wordwise Explanation:

The square of the final velocity equals the square of the initial velocity plus twice the product of acceleration and displacement. If a car accelerates from 0 to 20 m/s over a displacement of 100 meters, the acceleration can be calculated accordingly.

Graphical Representation of Motion

Graphs are powerful tools in physical science 11 for visualizing motion. Key types include:

Displacement-Time Graph

Shows how displacement varies with time. A straight line indicates constant velocity, while a curved line indicates acceleration.

Velocity-Time Graph

Illustrates how velocity changes over time. The slope of the line indicates acceleration, and the area under the graph represents displacement.

Acceleration-Time Graph

Displays how acceleration varies with time. A horizontal line indicates constant acceleration.

Practical Applications and Problem-Solving Tips

Applying wordwise answers in real-world situations helps deepen understanding.

- Break down the problem into known and unknown quantities.
- Identify the relevant equations of motion.
- Translate the problem into words, then convert to mathematical form.
- Calculate step-by-step, verifying units and signs.
- Use graphs where necessary to visualize motion.

For example, if a cyclist accelerates uniformly from 10 m/s to 20 m/s over 5 seconds, find the acceleration.

Solution in words:

Change in velocity divided by time gives acceleration.

Answer:

$$a = (20 \text{ m/s} - 10 \text{ m/s}) / 5 \text{ s} = 2 \text{ m/s}^2.$$

Summary of Key Terms in Motion

To excel in physical science 11, students should remember these essential terms:
