Question 2: Short Answer

Explain how seafloor spreading contributes to the movement of tectonic plates.

Sample Answer:

Seafloor spreading occurs at divergent boundaries, where magma rises from the mantle to create new oceanic crust. As new crust forms, it pushes the older crust away from the mid-ocean ridge, causing the plates to move apart. This process continuously renews the ocean floor and drives plate movement through the mechanism of ridge push and mantle convection.

Question 3: Diagram Interpretation

Given a diagram showing a collision between an oceanic and a continental plate, identify the features formed and explain the processes involved.

Sample Answer:

In this collision, the denser oceanic plate is subducted beneath the continental plate, forming a deep-sea trench. The subduction process causes melting of the subducted slab, leading to magma generation and volcanic activity inland, forming a volcanic mountain range. The collision also results in mountain-building and seismic activity.

Study Guide and Answer Key for Plate Tectonics

To facilitate effective studying, here's a guided answer key for common questions related to plate tectonics.

Q1: What is the theory of plate tectonics?

The theory of plate tectonics states that Earth's lithosphere is divided into several rigid plates that move over the semi-fluid asthenosphere beneath them. This movement explains geological phenomena such as earthquakes, volcanic activity, and mountain formation.

Q2: What are the main types of plate boundaries and their features?

There are three main types of plate boundaries:

- **Divergent Boundaries:** Plates move apart, creating new crust. Features include mid-ocean ridges and rift valleys.
- **Convergent Boundaries:** Plates move toward each other, forming mountain ranges, deep trenches, and volcanic arcs.
- **Transform Boundaries:** Plates slide past each other horizontally, causing earthquakes along faults like the San Andreas Fault.

Q3: What evidence supports the theory of plate tectonics?

Key evidence includes:

- Fit of the continents (e.g., South America and Africa)
- Fossil distribution across continents
- Matching rock formations and mountain ranges on different continents
- Distribution of earthquakes and volcanoes along plate boundaries
- Seafloor spreading and magnetic striping patterns on the ocean floor

Q4: How does seafloor spreading work?

Seafloor spreading occurs at divergent boundaries, where magma rises from the mantle to create new oceanic crust. As new crust forms, it pushes older crust away from the ridge, causing the seafloor to spread. Magnetic minerals in the crust record reversals in Earth's magnetic field, creating striped patterns that help date the spreading process.

Q5: What is subduction and where does it occur?

Subduction is the process where one tectonic plate sinks beneath another into the mantle at convergent boundaries. It primarily occurs at deep ocean trenches, such as the Mariana Trench, and is responsible for volcanic activity and the recycling of crust into Earth's interior.

Q6: Why do earthquakes tend to occur along plate boundaries?

Earthquakes are caused by the release of energy from the movement of plates along faults. Since most plate movements happen at boundaries, these regions experience the majority of seismic activity. Transform faults, subduction zones, and rift valleys are particularly earthquake-prone.

Important Study Tips for Mastering Plate Tectonics

Sample Questions and Answer Key Breakdown

Below are examples of typical questions in a plate tectonics study guide, along with detailed explanations to aid understanding.

Question 1: What causes the movement of tectonic plates?

Answer:

Plate movements are primarily driven by mantle convection, where heat from Earth's interior causes mantle material to circulate. This convection creates forces that push and pull plates. Additionally, ridge push at mid-ocean ridges and slab pull at subduction zones contribute to the movement.

Explanation:

- Mantle convection cells act like conveyor belts, moving plates.
- Ridge push occurs because new crust forms at divergent boundaries, pushing plates apart.
- Slab pull happens as denser, sinking oceanic plates pull the rest of the plate along.

Question 2: Describe the features of divergent plate boundaries.

Answer:

Features of divergent boundaries include:

- Mid-ocean ridges: Underwater mountain ranges created by upwelling magma.
- Rift valleys: Valleys formed on land where plates are pulling apart.
- Volcanic activity: Magma rises through the gap, leading to volcanic eruptions.
- Seafloor spreading: New oceanic crust forms as magma solidifies at the ridge.

Explanation:

As plates diverge, magma rises to fill the gap, creating new crust and pushing plates apart. This process results in the formation of features like the Atlantic Ocean's mid-ocean ridge.

Question 3: What are the differences between oceanic and continental crust?

Answer:

Feature	Oceanic Crust	Continental Crust
---------	---------------	-------------------

-----	-----	-----
-------	-------	-------

Composition	Dense basaltic rock	Less dense granitic rock
-------------	---------------------	--------------------------

Thickness	About 5-10 km	About 30-50 km
-----------	---------------	----------------

Age	Usually younger (up to 200 million years)	Can be billions of years old
-----	---	------------------------------

Density	Higher	Lower
---------	--------	-------

Explanation:

Oceanic crust is thinner and denser, making it more prone to subduction. Continental crust is thicker and less dense, contributing to the formation of mountain ranges.

Question 4: How do earthquakes relate to plate boundaries?

Answer:

Most earthquakes occur along plate boundaries due to the movement and interaction of plates. The release of stress along faults causes seismic waves, which are felt as earthquakes.

- Transform boundaries: Earthquakes result from lateral sliding motion.
- Convergent boundaries: Earthquakes occur as plates collide or subduct.
- Divergent boundaries: Earthquakes happen as plates pull apart and new crust forms.

Explanation:

Understanding where earthquakes happen helps in assessing seismic hazards and understanding plate dynamics.
